

Does pre-primary education reach those who need it most?

- Attendance in pre-primary education is associated with better student performance later on.
- Fifteen-year-old students in 2012 were more likely than 15-year-olds in 2003 to have attended at least one year of pre-primary education.
- The gap in pre-primary attendance rates between socio-economically advantaged and disadvantaged pupils is growing.

As is true for nearly every endeavour, the better prepared one is, the greater the likelihood of success. Education is no exception. Young children who have learned how to behave in groups and have been introduced to the basics of letters and numbers tend to be more open to and ready for the school experience than children who haven't. Pre-primary education serves this purpose well; and if all children, regardless of their socio-economic status, had access to high-quality pre-primary programmes, these programmes could also help to reduce the inequities in readiness for school that are related to pupils' family backgrounds. But results from PISA 2012 find that disadvantaged students are disproportionately missing out on this formative education opportunity.

Enrolment
in pre-primary education
is expanding...

PISA consistently finds that 15-year-old students who had attended pre-primary education tend to perform better than those who had not attended pre-primary education, even after accounting for the students' socio-economic status. In 2012, in OECD countries that participated in both PISA 2003 and 2012, the difference in PISA mathematics scores between these two groups of students was 51 points – the equivalent of markedly more than a year of formal schooling.

In 2012, 93% of students across OECD countries reported that they had attended pre-primary education; three out of four students (75%) reported that they had attended pre-primary education for more than one year. In 36 of 40 countries and economies that participated in PISA 2003 and 2012, over 80% of students reported that they had attended pre-primary education; however, in Indonesia and Tunisia, between 38% and 46% of students reported that they had not, as did 70% of students in Turkey.

Attendance in pre-primary education has grown substantially over the past decade. In 2003, 69% of 15-year-olds across the OECD countries that have comparable data between 2003 and 2012 reported that they had attended pre-primary school for more than one year; in 2012, 75% of students reported so. During that period, the United States saw a marked increase of more than 60 percentage points in the share of students who had attended pre-primary school for more than one year. The proportion of students in Denmark, Ireland, Latvia, Sweden and Thailand who had attended pre-primary school for more than one year swelled by at least 10 percentage points between 2003 and 2012.

The relationship between students' mathematics performance and their attendance in pre-primary school is growing stronger

Score-point difference in mathematics performance between students who reported that they had attended pre-primary education for more than one year and those who hadn't

Notes: The change in the score-point difference in mathematics performance between 2003 and 2012 (2012 - 2003) is shown above the country/economy name. Only statistically significant differences are shown.

OECD average 2003 compares only OECD countries with comparable mathematics scores since 2003.

Countries and economies are ranked in descending order of the score-point difference in mathematics performance between students who reported in 2012 that they had attended pre-primary education (ISCED 0) for more than one year and those who hadn't.

...but not among the pupils who could benefit the most.

While 15-year-old students in 2012 were more likely than 15-year-olds in 2003 to have attended at least one year of pre-primary education, pre-primary enrolment is higher among advantaged students than disadvantaged students, and higher among students attending advantaged schools than those attending disadvantaged schools. For example, in 2012, an average of 67% of disadvantaged students had attended pre-primary education for more than one year, while 82% of advantaged students had done so. This difference in enrolment between advantaged and disadvantaged students

is observed in almost all PISA-participating countries and economies. It is largest – 48 percentage points – in Poland, and between 25 and 30 percentage points in Portugal, the Slovak Republic and Uruguay. This means that the students who could benefit the most from these programmes – those from disadvantaged backgrounds – are less likely to participate in them. This socio-economic divide widened in the Slovak Republic between 2003 and 2012 as it did, to a lesser extent, in Finland, Greece, Latvia, Luxembourg, Poland and the Russian Federation; it narrowed, however, in Germany, Korea, Macao-China, Portugal and Uruguay.

The socio-economic divide in pre-primary enrolments is widening

Index-point difference in the PISA index of economic, social and cultural status between students who reported that they had attended pre-primary education for more than one year and those who hadn't

Notes: The change in the index-point difference in the PISA index of economic, social and cultural status between 2003 and 2012 (2012 - 2003) is shown above the country/economy name. Only statistically significant differences are shown.

OECD average 2003 compares only OECD countries with comparable values on the PISA index of economic, social and cultural status since 2003.

Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

Countries and economies are ranked in ascending order of the index-point difference in the PISA index of economic, social and cultural status between students who reported in 2012 that they had attended pre-primary education (ISCED 0) for more than one year and those who hadn't.

PISA

IN FOCUS

At the same time, the performance gap between students who had attended pre-primary school and those who had not also widened between 2003 and 2012. In 2003, students who had attended pre-primary education scored 40 points higher in mathematics, on average, than students who had not; by 2012, that difference had grown to 51 score points. This difference in mathematics performance grew by more than 25 score points in the Czech Republic, Finland, Greece, Iceland, Italy, Luxembourg, the Slovak Republic, Spain and Thailand. In all of these countries, pre-primary enrolment rates increased significantly during the period; in Finland, Luxembourg and Portugal, they grew by more than five percentage points.

One reason for the increase in the performance gap lies in the fact that 15-year-old students who had not attended pre-primary education tend to be more socio-economically disadvantaged. Given the overall growth in participation rates, students who reported in 2012 that they had not attended pre-primary education may have come from particularly disadvantaged backgrounds. Taken together, these findings show a strong relationship between attendance in pre-primary school and higher scores in mathematics later on.

The bottom line: PISA results consistently show that a 15-year-old student – regardless of his or her background – who had attended pre-primary school for at least one year performs better in mathematics than a student who hadn't. That pre-primary enrolment rates are growing faster among advantaged students than among disadvantaged students signals that countries have to work harder to ensure that all families, particularly disadvantaged families, have access to high-quality pre-primary education, and to information about such programmes, near where they live. An investment in early education, both for parents and for governments, pays dividends later on in life.
